The salinity of sea water influences the solubility of calcium carbonate in the water because of its relations to (1) the solubility of free carbon dioxide in the water, (2) the constants, K^* , K_2' , and $K_{c\&CO_2}$ (3) the hydrogen-ion concentration, and (4) the quantity of calcium and excess base in the water.

Buoyancy is directly affected by the density of water: the more dense water is, the more buoyancy it will have. The greater the salinity of water, the greater its density; salinity, therefore, increases buoyancy.

Evaporation of ocean water and formation of sea ice both increase the salinity of the ocean. However these "salinity raising" factors are continually counterbalanced by processes that decrease salinity such as the continuous input of fresh water from rivers, precipitation of rain and snow, and melting of ice.
